Definition

Git: is a **distributed** open source **version control system(VCS)** which gives us an efficient control over our projects.

In short, it's a file tracking system.

What is a "distributed system"?

It is a system which provide a platform for developers or partners to work on the same project with out being in the same server.

What is "Version Control System"?

It manages and records changes to a files, documents, codes and projects over time so that we can recall a specific version at a later time (it's a time travel with in files).

Git provides three working areas and it's critical to understand this three terms:

Working directory or local copy

This are the files you are editing and that will be in the next commit.

Staging area or index area

It is an intermediate space to store files scheduled for the next commit.

Repository

It is a subdirectory named `.git` and contains the whole history of your project.

A typical workflow of any Git project takes the following pattern:

- 1 Modify files in your working directory.
- 2 Add a file to the staging area.
- 3 Commit a file to the git directory.

Figure: A typical workflow of Git project.

Why we need to use Git?

- the life history of a file is recorded from the beginning so that, you can inspect any vision of the file by the author, time and content.
- at any moment you can revert to a previous vision of your file.
- it provides simpler approach for coordinated work between multiple developers.
- it displays the differences between each versions.
- it allows to work locally at your machine, with a remote repository and synchronizing both.
- it allows to work on multiple variants of one project as branches and merge them easily when needed.

Installing Git

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

Basically, you can use Git in two ways. The **command line** and the **graphical user interfaces (GUIs)**. This tutorial is prepared based on the command line. If you know how to use Git on command line, then using it in GUIs will be come easier for you.

In Ubuntu the installation is simple, type the following command on the terminal and press enter:

Code for Git installation

```
sudo apt-get install git-core
```

For further instructions on how to install Git on Linux systems can be found at <http://git-scm.com/download/linux>

To check the version of Git

```
git --version
```

Configuring Git

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

It's mandatory to setup your user name and email address, for credential purpose.

Replace the username and email address with your with your own.

Code for Configuration

```
git config --global user.name [user name]
git config --global user.email [e-mail address]
```

To colorize the output with different colors use the following code:

Code for setting the color output

```
git config --global color.ui auto
```

To check for the configuration of Git:

Code for checking configuration

```
git config --list
```

Configuring Git ii

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

Specifically, to check for the user name and email address:

Code for Git configuration

```
git config user.name  
git config user.email
```

Remark

The configuration of Git must be done at once. If you want to use a different name/email address for a particular project. You can change it by navigating to the project directory and use the configure command but leaving out the "--global" part.

Configuration code for a particular project

```
cd [project directory]  
git config user.name [user name]  
git config user.email [e-mail address]
```

Getting Help

For getting help about Git commands, use the following methods and don't forget to replace the term [verb] by the command name.

Code for help

```
git help <verb>  
git <verb> --help
```

A precise and quick reference on Git command's can be obtained using the following command:

Code for specific help

```
git <verb> --h
```

You can learn more about the individual Git commands using the following code:

Code for getting detail information on Git commands

```
man git  
man gitglossary
```

Initializing Git

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

To initialize a local repository, use the `[git init]` command.

First create a folder or move to an existing directory where you want to track your files:

Code for initializing Git

```
cd [folder name]
git init [Repository name]
```

This creates a new repository with `.[git]` extension and will contain a full history your project. It's also a hidden so that you can use the `[list all]` command to view it.

Code to viewing hidden files

```
ls -la
```

Git status checking

At any stage, it's important to review the current state of your file, for that use the `[git status]` command.

Code for checking the file status

```
git status
```

You may find your file either as tracked or untracked file:

Untracked files: are files that are not known by Git.

Tracked files: are files that were in the last snapshot; they can be unmodified, modified, or staged (files known by Git).

If you need a summarized output of the Git status, use the following command:

Code for summarized output

```
git status -s
```

?? new files that are not tracked

A new files that have been added to the staging area

M modified files

Git Ignore

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

Sometimes there are files you don't want to track or show to others. In this scenario, first you have to create `[.gitignore]` file as follow:

Code for creating `.gitignore` file

```
touch .gitignore
```

The next step is to open the `[.gitignore]` file using a text editor and enter file names & extensions as described bellow:

Code for editing `.gitignore` file

`[file.log]` it tells Git to ignore a file named `[file.log]`

`[*.log]` it tells Git to ignore all files with `[.log]` extension.

`[/dir]` it tells Git to ignore a directory named `[dir]`

Then run `[git status]` command to see those files are under untracked category.

Git Staging

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

To begin tracking a file, you can use the `[git add]` command followed by the file name with its extension.

Code for staging a single file

```
git add [file name]
```

It's possible to add files using wildcard. In this case, all files with the specified extension will be added to the staging area.

Code for staging using a wildcard

```
git add *.[extension name]
```

You can add all files at once using the following command:

Code to stage all files

```
git add -A
```

Sometimes you need to remove a file from Git. You can either remove the file from staging area or completely from your working directory.

To remove a file from staging area to unstaged area, use the following command and it will show up under the "Changes not staged for commit":

Code for removing files from staging area

```
rm [file name]
```

To completely delete a file from the working directory and stage it to deletion you can use the following command as a result file will be gone and no longer tracked.

Code for completely removing files from Git

```
git rm [file name]
```

To remove the file from version control system but to preserves it in working directory, you can use the following command:

Code for removing files but keeping it in the working directory

```
git rm --cached [file name]
```

To completely remove the Git directory, use the following command:

Code for removing Git directory

```
rm -rf .git
```

If you want to rename a file in Git, use the following command:

Code for renaming a file

```
git mv [file-original] [file-renamed]
```

Resetting changes in Git

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

The rest command is used when you want to cancel current changes from the staging area back to the previous version or commit.

If you want to reset a file to the last commit ignoring the changes, use the following command:

Code for resting a single file

```
git reset [file name ]
```

To reset all files at once from staging area, use the following command:

Code for resting all files

```
git reset
```

To overwrite all changes in the staging area and in the working copy, use the following command:

Code for resting all changes

```
git reset --hard
```

Git Commits

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

The Git commit command makes a "snapshot" of your staged files and saves it permanently in the git database.

To commit changes to the repository, use the following command:

Code for committing files

```
git commit -m"reason for the commit"
```

Important [-m]

The comments should describe the rationale behind your changes.

By running a variety of [git log] commands, you can get information about the commit history of a file such as who make the changes (author), when(time) and why(reason).

To show the commit history for the currently active branch, use the following command:

Code for displaying version history

```
git log
```

To display the full difference between each of consecutive versions, use the following command:

Code for viewing the difference b/n each versions

```
git log -p
```

It's possible to decide the total number of versions to be displayed by setting the desired number.

Code for viewing fixed number of versions

```
git log -[number of version required]
```

If you want a summarized output as a single lines, use the following command:

Code for viewing summarized history

```
git log --oneline
```

Sometimes you may want to know the number of lines inserted or deleted from each version, for that use the following command:

Code to view the number of deletion/insertion of each version

```
git log --stat
```

Another tool which is used to show the differences or review history between two revisions is the [git diff] tool.

To know the difference between the index (staging area) and the working copy, use the following command:

Code to review difference between index and working copy
git diff

To know the difference between the index (staging area) and the last commit/version, use the following command:

Code to review difference between index and last commit
git diff --staged

Git Inspecting & Comparing tools iv

A branch is a parallel version of your default repository mainly the master branch. It can be used for experimental purpose.

To know in which branch you are working, you can use the `[git branch]` command:

Code for knowing your current branch

```
git branch
```

Your current branch will have `[*]` in-front of the branch name.

To create a new branch use the `git branch` command followed by the new branch name:

Code for creating a new branch

```
git branch [New branch name]
```

If you want to merge a single branch to a master branch, first go to the master branch then use the `[git merge]` command followed by branch name.

Code for merging branches

```
git checkout master  
git branch --merged  
git merge [branch name]
```

Sometimes you want to switch to other branches with out loosing your current work. In this case, run the first command before going to other branches and after returning to the original branch run the second command:

Code for not loosing intermediate work

```
git stash  
git stash apply
```

Cloning a remote repository i

[Introduction to GIT](#)[Advantages of using Git](#)[Installing Git](#)[Configuring Git](#)[Getting Help](#)[Initializing Git](#)[Git status checking](#)[Git Ignore](#)[Git Staging](#)[Removing & Renaming in Git](#)[Resetting changes in Git](#)[Git Commits](#)[Git Inspecting & Comparing tools](#)[Git Branching](#)[Cloning a remote repository](#)[Example](#)[Further Reading](#)

Working with remote repositories is one of the primary features of Git. As a result, you may need to download a remote repository into your local machine.

To get a copy of an existing repository, use `[git clone]` command:

Code for cloning a remote repository

```
git clone [url]
```

It's possible to clone the repository with the different name:

Code for cloning with d/f name

```
git clone [url] new name
```

Login into your GitHub account using your username and password. If you don't have account go to the following site <https://github.com/login> and create a GitHub account. You need to have a valid email address.

Once you have a GitHub account, create a new repository as follow:

- Give a repository name, in this example, [Git_tutorial], you can use your own name.
- Description [optional]
- Choose the public option
- In you want initialize it with readme file [Optional]
- Click on create repository
